7	Enterprise Architecture Evaluation	4

1 Introduction

This section is to give a general introduction to the company, including a description of its main product offerings, markets and strategy.

2 Value Network Analysis

This section is to show the value network in which the company will work. Agents, resources, and exchanges of resources are to be made explicit. Note

that the project group here has to clarify exactly which products the company is to offer. Also note that the value network analysis has to take into account that the company is to work in different markets with different actors.

2.1 VDML Diagram

Include a VDML diagram here

2.2 VDML Diagram Explained

Include a textual description explaining the VDML diagram

3 Goal Design

This section is to show the goals of the company. The goals shall be clearly related to the value network analysis in Section 1. In order to identify relevant goals, the project group shall make use of the five forces model and generic strategies of Michael Porter (see links on the page “Reading Resources” at the course web site). It is recommended that Strategy maps be used to structure the goal model (see link on the same page).

3.1 Goal Model

Include a graphical BMM goal model here

3.2 Goal Model Explained

Include a textual description of the BMM model that explains it and shows how it is related to the components of the five forces model

4 Process Design

This section is to show the processes of the company. The processes shall be clearly related to the value network analysis in Section 2 and the goal design in Section 3.

4.1 Exchange and Conversion Processes in REA

Include a graphical conceptual schema of the company with exchange and conversion processes (expressed as UML class diagrams) using the REA ontology. All classes including attributes must be named and the cardinality/multiplicity between the classes must be expressed. Stereotypes for all classes shall be specified in accordance with REA. Note that only the exchange and conversion processes within the company shall be modelled, but not processes in other companies in the value network. The conceptual schema shall also make use of

other relevant patterns than those for exchange and conversion processes, i.e. structural and behavioural patterns as defined in the book by Hruby. Provide textual descriptions for explaining the graphical schema.

4.2 Detailed Processes in EPC

Include a number of detailed process models, expressed as EPC diagrams. The processes should include sales and procurement. The process models should show actions of individual actors and handle alternatives and exceptions. It is recommended to make each process diagram small by using the decomposition mechanisms of EPC diagrams.

4.3 Relationships between Models

Include one or several tables that visualize the relationships between the models introduced in this section and the models in the previous sections. The tables should help to answer the following questions:

- How does the design of the processes help in fulfilling the goals of the company?
- What are the relationships between the exchange and conversion processes and the EPC models?
- What are the relationships between the EPC models and the VDML diagram?

5 IT Architecture Design

This section is to show the IT architecture of the company. The IT systems to be used in the company are to be specified, including BPMS, CRM, ERP, DW, BI tools, dashboard, and KM. The use of EAI and decision support systems (BI, DW and Dashboards) shall also be discussed. The IT architecture shall be documented graphically in a diagram showing the systems and the data flows between them, representing systems as nodes and data flows as labeled arrows. The relationships between the systems and the business processes they support shall be made explicit.

6 Business Performance Management

This section is to introduce the key performance indicators (KPI) for measuring and analysing the business processes of the company.

6.1 Leading and Lagging KPIs

Include between five and ten leading and lagging indicators. Each indicator shall be described in an indicator template consisting of at least the following parts: name of the indicator, definition of the indicator, which goal(s) in the company's goal model that the indicator is related to, target values, which part of a business process (i.e. which activity) the indicator measures, which IT system that will be the data source for the indicator, and which type of IT solution will feed the dashboard system with data from the source system. Ensure that the descriptions are consistent with the IT architecture in Section 5.

6.2 Evaluation of KPIs

Include an evaluation of the KPIs from the previous subsection, based on the article by Eckerson.

7 Enterprise Architecture Evaluation

In other parts of the work you have designed the organization from several perspectives, goals, processes, IT architecture, and so on. All of these combined converge towards an Enterprise Architecture (EA). A key component of EA is capability, an ability and capacity that enable an enterprise to achieve a business goal in a certain context. In this light, your task is to design one capability based on the models already created. The first step is to fill in the capability elicitation template in terms of relevant goals, KPIs, context, business process variants. This should be followed by a graphical design of a capability model, for instance, by introducing links between the newly developed capability and the corresponding constructs in other models.
